Abstract

From nuclear materials accountability to detection of special nuclear material, SNM, the need for better modeling of fission has grown over the past decades. Current radiation transport codes compute average quantities with great accuracy and performance, but performance and averaging come at the price of limited interaction-by-interaction modeling. For fission applications, these codes often lack the capability of modeling interactions exactly: energy is not conserved, energies of emitted particles are uncorrelated, prompt fission neutron and photon multiplicities are uncorrelated. Many modern applications require more exclusive quantities than averages, such as the fluctuations in certain observables (e.g. the neutron multiplicity) and correlations between neutrons and photons. The new computational model, FREYA 2.0.1 (Fission Reaction Event Yield Algorithm), aims to meet this need by modeling complete fission events. Thus it automatically includes fluctuations as well as correlations resulting from conservation of energy and momentum. FREYA 2.0.1 has been integrated into the LLNL Fission Library 2.0.1, and will soon be part of MCNP6.2, TRIPOLI-4.10, and Geant4.10.

1 Introduction

Several general-purpose Monte Carlo codes (MCNP/X [1–5], TART [5,6], COG [5,7], Geant [8], etc.) are currently available for modeling neutron transport. To model fission, they employ the “average fission model”, which is characterized by outgoing projectiles (fission neutrons and photons) that are uncorrelated and sampled from the same probability density function. This approximation is sufficient for the calculation of average quantities such as flux, energy deposition and multiplication. However, it is unsuitable for studying detailed correlations between neutrons and/or photons on an event-by-event basis.

During the past decade several code extensions have been developed that allow the modeling of correlations in fission. MCNP-DSP [5,9] and MCNPX-PoliMi [5,10] added angular correlations of fission neutrons by assuming the $^{252}$Cf spontaneous fission distribution can be employed for all fissionable nuclides. Both codes also include detailed multiplicity and energy distributions for prompt fission photons time correlated with the fission event. A new option was introduced in MCNPX2.7.0 [11] for the treatment of fission events utilizing a library developed at LLNL [12]. It features time-correlated sampling of photons from neutron-induced fission, photofission and spontaneous fission. The capabilities for correlations are, however, limited for these last 3 options (MCNP–DSP, MCNPX–PoliMi, LLNL Fission Library), as they sample outgoing particles from average fission distributions instead of sampling them from individual realizations of a fission process.

In recent years, various simulation treatments have made it possible to also address fluctuations of and correlations between fission observables. In particular, a Monte Carlo approach was developed [13, 14] for the sequential emission of neutrons and photons from individual fission fragments in binary fission. The more recent event-by-event fission model, FREYA, includes more fission isotopes and has been specifically designed for producing large numbers of fission events in a fast simulation [15–20]. Employing nuclear data for fragment-mass and kinetic-energy distributions, using statistical evaporation models for neutron and photon emission, and conserving energy, momentum, and angular momentum throughout, FREYA is able to predict a host of correlation observables, including correlations in neutron multiplicity, energy, and angles, and the energy sharing between neutrons and photons.

The stand-alone fission event generator FREYA was integrated into the LLNL Fission Library, which is an integral part of the transport codes MCNPX2.7.0, MCNP6, TRIPOLI-4.9 [21], and Geant4.10.

The first part of this paper will focus on the physics in the FREYA fission model and the algorithmic implementation thereof, the second part will describe the data files required by FREYA, while the third part will show how to use FREYA within the LLNL Fission Library.

2 Fission model and algorithm

The computational model FREYA generates complete fission events, i.e. it provides the full kinematic information on the two product nuclei as well as all the emitted neutrons and photons. In its development, an emphasis had been put on speed, so large event samples can be generated fast, and FREYA therefore relies on experimental data supplemented by simple physics-based modeling.

The algorithmic flow of FREYA is illustrated in Figs. 1-8. Blue boxes indicate entry points, parallelograms input parameters, cylinders data files, diamonds decision points, pentagons off page connectors, orange ovals outputs, and dice indicate sampling.

FREYA models the fission of excited nuclei. Finite excitation energies can be generated in a variety of ways, including electromagnetic agitation and, more commonly for current applications, absorption of a neutron by a fissile nucleus. In this case, the fissile nucleus $^{A_0}Z_0$ is in its ground state $E_0^* = 0$ before the incident neutron is absorbed, see blue box in Fig. 1; $Z_0$, $A_0$, and $E_n$ are entered where $E_n$ is the kinetic energy of the incoming neutron absorbed by the specified fissile nucleus $^{A_0}Z_0$. In its simplest version, FREYA assumes that the initial
nucleus $^{A_0}Z_0$ is at rest, therefore $P_0 = 0$.

Depending on its degree of excitation, the system may emit one or more neutrons prior to fission, either by pre-equilibrium emission (at the highest excitations) or by (possibly sequential) pre-fission evaporation which may continue as long as the excitation energy exceeds the neutron separation energy. The two processes are described in Figs. 1-2.

In the case of spontaneous fission, the fissile nucleus $^{A_0}Z_0$ fissions with no prior neutron absorption, and the excitation energy of the nucleus is $E_0^* = 0$, see blue box in Fig. 3.

After the system is prepared for either neutron-induced or spontaneous fission, the fission fragments are selected by sampling, as described in Fig. 3. The scission process is finalized by determining the fission $Q$ value, as in Fig. 4. The fission fragment kinetic and excitation energies are then determined, as shown in Figs. 5-6. Finally, neutron evaporation and photon emission from the fragments, as shown in Figs. 7-8, complete the fission event.

This section is divided into three parts to describe the physics behind the algorithms in FREYA. The system pre-fission is described in Sec. 2.1. Next, the scission process itself that results in binary fission with two excited fission fragments is treated in Sec. 2.2. Finally, de-excitation by post-fission radiation of neutrons and photons is described in Sec. 2.3.

2.1 Pre-fission radiation

In addition to spontaneous fission, FREYA treats neutron-induced fission up to $E_n = 20$ MeV. There are two possible ways for neutrons to be emitted before fission occurs for sufficiently high incident neutron energies: pre-equilibrium neutron emission (which plays a role at the highest energies) and pre-fission neutron evaporation, referred to as multichance fission. FREYA handles both these possibilities.

2.1.1 Pre-equilibrium neutron emission

Pre-equilibrium neutron emission occurs if a neutron is emitted before the compound nucleus is equilibrated. In this case, a non-equilibrium model employing a two-component exciton model that represents the evolution of the nuclear reaction in terms of time-dependent populations of ever more complex many-particle-many-hole states is used. See Ref. [18] for more details.

Figure 1: Pre-equilibrium neutron emission, associated with neutron-induced fission.
A many-exciton state consists of $p_{\nu}(\pi)$ neutron (proton) particle excitons and $h_{\nu}(\pi)$ neutron (proton) hole excitons. The total number of neutron (proton) excitons in the state is $n_{\nu}(\pi) = p_{\nu}(\pi) + h_{\nu}(\pi)$. Processes that reduce the number of excitons are neglected. The pre-equilibrium neutron emission spectrum is then given by

$$
\frac{d\sigma_{P}}{dE} = \sigma_{\text{CN}} \sum_{p_{\pi}=0}^{p_{\pi}^{\text{max}}} \sum_{p_{\nu}=0}^{p_{\nu}^{\text{max}}} W(p_{\pi}, h_{\pi}, p_{\nu}, h_{\nu}, E) \tau(p_{\pi}, h_{\pi}, p_{\nu}, h_{\nu}) P(p_{\pi}, h_{\pi}, p_{\nu}, h_{\nu})
$$

where $\sigma_{\text{CN}}$ is the compound nuclear cross section (usually obtained from an optical model calculation), $W$ is the rate for emitting a neutron with energy $E$ from the exciton state $(p_{\pi}, h_{\pi}, p_{\nu}, h_{\nu})$. $\tau$ is the lifetime of this state, and $P(p_{\pi}, h_{\pi}, p_{\nu}, h_{\nu})$ is the (time-averaged) probability for the system to survive the previous stages and arrive at the specified exciton state. In the two-component model, contributions to the survival probability from both particle creation and charge exchange need to be accounted for. The survival probability for the exciton state $(p_{\pi}, h_{\pi}, p_{\nu}, h_{\nu})$ can be obtained from a recursion relation starting from the initial condition $P(p_{\nu}=1, h_{\nu}=0, p_{\pi}=0, h_{\pi}=0) = 1$ and setting $P=0$ for terms with negative exciton number.

For each event generated, FREYA first considers the possibility of pre-equilibrium neutron emission and, if it occurs, a neutron is emitted with an energy selected from the calculated pre-equilibrium spectrum, Eq. (1). The possibility of equilibrium neutron evaporation is then considered, starting either from the original compound nucleus, e.g. $^{240}\text{Pu}^{*}$ for $^{239}\text{Pu}(n,f)$, or the less excited nucleus, $^{239}\text{Pu}^{*}$, remaining after pre-equilibrium emission has occurred. Neutron evaporation continues until the excitation energy of a daughter nucleus is below the fission barrier (in which case the event is abandoned and a new event is generated) or the nucleus fissions.

A flow chart for pre-equilibrium neutron emission is shown in Fig. 1. One should note that pre-equilibrium neutron emission is very improbable, on average 0.10 pre-equilibrium neutrons are emitted at $E_{n} \sim 14 \text{ MeV}$, see Fig. 2 in Ref. [18]. After this first process, the excited nucleus can also undergo pre-fission neutron evaporation, discussed next.

2.1.2 Pre-fission neutron evaporation

![Figure 2: Pre-fission evaporation, associated with neutron-induced fission.](image)

In multichance fission or pre-fission neutron evaporation — shown in Fig. 2 — neutron evaporation can occur from the compound nucleus as long as the excitation energy of the compound exceeds the neutron sepa-
ration energy, $S_n$. One or more neutrons can be emitted before fission. The probability for pre-fission neutron evaporation is determined by the competition between fission and neutron evaporation. At higher incident neutron energies, neutron evaporation from the compound nucleus competes more favorably with direct (first chance) fission.

The criterion for pre-fission evaporation is based on $\Gamma_n(E^*)/\Gamma_f(E^*)$, the relative magnitudes of the neutron evaporation and fission decay widths at a given excitation energy $E^*$ [22],

$$\frac{\Gamma_n(E^*)}{\Gamma_f(E^*)} = \frac{2g_s\mu_n\sigma}{\pi\hbar^2} \frac{\int_0^{X_n} (X_n - x)\rho_n(x)dx}{\int_0^{X_f} \rho_f(x)dx}, \quad (2)$$

where $g_s = 2$ is the spin degeneracy of the neutron, $\mu_n$ is its reduced mass, and $\sigma = \pi R^2 = \pi r_0^2 A^{2/3}$. Here $\rho_n(x)$ is the level density in the evaporation daughter nucleus at excitation energy $x$. The maximum value of $x$ is given $X_n = Q_n = E^* - S_n$, where $Q_n$ is the $Q$ value for neutron emission and $S_n$ is the neutron separation energy. Similarly, $\rho_f(x)$ is the level density of the fissioning nucleus when its shape is that associated with the top of the fission barrier. The excitation $x$ is measured relative to the barrier top with a maximum value of $X_f = E^* - B_f$, where $B_f$ is the height of the fission barrier.

Neutron evaporation is possible whenever the excitation energy of the compound nucleus is larger than the neutron separation energy, $E^* > S_n$, a positive quantity because it costs energy to remove a neutron from the nucleus. The excitation energy of the evaporation daughter nucleus is $E_{d}^* = E^* - S_n - E$ where $E$ is the kinetic energy of the relative motion between the emitted neutron and the daughter nucleus. If this quantity exceeds the fission barrier in the daughter nucleus, then second-chance fission is possible. The same procedure is then applied to the daughter nucleus, so that further pre-fission neutron emission possible. As the incident neutron energy is increased, emission of further pre-fission neutrons becomes possible and the associated fission events may be classified as first-chance fission (when there are no pre-fission neutrons emitted), second-chance fission (when one neutron is emitted prior to fission), and so on. See Fig. 1 of Ref. [18] for a plot of the multichance fission probability up to $E_n = 20$ MeV for $^{239}$Pu$(n,f)$.

Emitted neutron kinetic energies are sampled using an algorithm similar to neutron evaporation explained in Sec. 2.3.1. For more discussion, see Ref. [18].

After both pre-equilibrium neutron emission and pre-fission neutron evaporation, the excitation energy is adjusted and the energy at which the yields are sampled is reduced accordingly.
2.2 Fission

After prefission radiation, the physics issue concerns how the mass and charge of the initial compound nucleus is partitioned among the two fission fragments and how the available energy is divided between the excitation of the two fragments and their relative kinetic energy.

2.2.1 Fission fragment mass and charge distributions

The current understanding of the fission process is that the evolution from the initial compound nucleus to two distinct fission fragments occurs gradually as a result of a dissipative multidimensional evolution of the nuclear shape. Because no quantitatively reliable theory has yet been developed for this process, we employ empirical evidence as a basis for selecting the mass and charge partition.

To treat a given fission case, we need the fission fragment mass distribution \( Y(A_f) \) and the total kinetic energy \( \text{TKE}(A) \) for the particular excitation energy considered. \( Y(A_f) \) is taken either directly as the measured yields or as a five-gaussian fit to the data which makes it possible to parametrize its energy dependence.

\[ \text{Sampling of fission fragment mass partition } A_H \text{ and } A_L \]

\[ \text{Sampling of fission fragment charge partition } Z_H \text{ and } Z_L \]

For this, we follow Ref. [24] and employ a Gaussian form

\[ P(Z_f|A_f) \propto \exp \left( -\frac{(Z_f - Z_f(A_f))^2}{2\sigma_Z^2} \right) \]  

(3)

Figure 3: Selection of fission fragments, applicable both to neutron-induced and spontaneous fission.

The compound nucleus left after prefission radiation undergoes binary fission into a heavy \( A_H Z_H \) and a light fragment \( A_L Z_L \), see Fig. 3. The mass split based on \( Y(A_f) \) is first selected. The fragment masses are obtained from experimental mass yields \( Y(A_f) \) — see Refs. [15, 17] — in the case of spontaneous fission. For neutron-induced fission, the energy dependence of \( Y(A_f) \) has been modeled for incident neutron energies of up to 20 MeV [18]. When data are not available for the mass yields \( Y(A_f) \), the mass number \( A_f \) of one of the fission fragments is selected randomly from a probability density \( Y(A_f) \) for which we employ five-Gaussian fits to the product mass number distribution [23] shifted upward in mass to ensure a symmetric distribution of the primary fragments. Sec. 3.7 covers the five-Gaussian fits in more detail.

The charge partition is selected subsequently from the associated conditional probability distribution \( P(Z_f|A_f) \). For this, we follow Ref. [24] and employ a Gaussian form
suggested by experiment [18] with the condition \( |Z_f - Z_f(A_f)| \leq 5\sigma_Z \). The centroid is determined by requiring that the fragments have, on average, the same charge-to-mass ratio as the fissioning nucleus \( Z_f(A_f) = A_f(Z_f/A_f) \). The charge of the complementary fragment then follows using \( Z_L + Z_H = Z_f \).

2.2.2 Fragment energies

Once the mass and charge of the two fragments have been selected, the linear and angular momenta of the two fragments and their internal excitations are sampled. The \( Q \)-value of the fission channel is the difference between the total mass of \( A_0 \) and the fragment ground-state masses,

\[
Q_{LH} = M(A_0)c^2 - M_Lc^2 - M_Hc^2.
\]  

(Figure 4: Scission, applicable both to neutron-induced and spontaneous fission.)

FREYA takes the required nuclear ground-state masses from the compilation by Audi and Wapstra [25], supplemented by the calculated masses of Möller et al. [26] when no data are available. This simple process is shown in Fig. 4.

Figures 5-6 shows how the fission fragment energies are selected. The \( Q_{LH} \) value is divided between the total kinetic energy (TKE), the total rotational and statistical excitations of the fragments. The average TKE is assumed to take the form

\[
TKE(A_H, E_n) = TKE_{data}(A_H) + dTKE(E_n).
\]  

(5)

The first term is extracted from data on thermal neutrons while the second is adjusted to the measured average neutron multiplicity, \( \langle N \rangle \).

After the average total fragment kinetic energy, \( \overline{TKE} \), has been calculated, the energy available for rotational and statistical excitation of the two fragments is then

\[
E_{sc}^* = Q - TKE
\]  

(6)

and the corresponding 'scission temperature' \( T_{sc} \) is obtained from

\[
E_{sc}^* = (A_0/e_0)T_{sc}^2.
\]  

(7)

The inclusion of angular momentum in FREYA was described in Ref. [20]. The overall rigid rotation of the dinuclear configuration prior to scission, caused by the absorption of the incoming neutron and the recoil(s) from any evaporated neutron(s), dictates certain mean angular momenta in the two fragments. In addition,
due to the statistical excitation of the scission complex, the fragments also acquire fluctuations around those mean values. FREYA includes fluctuations in the wriggling and bending modes (consisting of rotations in the same or opposite sense around an axis perpendicular to the dinuclear axis) but ignores tilting and twisting (in which the fragments rotate around the dinuclear axis). These dinuclear rotational modes are assumed to become statistically excited during scission and they are therefore described by Boltzmann distributions,

\[ P_\pm (s_\pm) \, ds_\pm^x \, ds_\pm^y \sim e^{-s_\pm^2/2I_{\pm}T} \, ds_\pm^x \, ds_\pm^y , \]  

(8)

where \( s_\pm = (s_\pm^x, s_\pm^y, 0) \) is the spin of the normal modes with plus referring to the wriggling modes (having parallel rotations) and minus referring to the bending modes (having opposite rotations). The corresponding moments

\[ \langle s_\pm^2 \rangle = I_{\pm}T , \]

\[ \langle s_\pm^x \rangle = 0 , \]

\[ \langle s_\pm^y \rangle = 0 . \]
of inertia are denoted $I_{\pm}$ [19, 20]. The degree of fluctuation is governed by the ‘spin temperature’

$$T_S = c_{TS}T_{sc}$$

(9)

(see Eq. (9)) which can be adjusted by means of the parameter $c_{TS}^1$. The fluctuations vanish for $c_{TS} = 0$ so the fragments emerge with the angular momenta dictated by the overall rigid rotation of the scission configuration (which is usually very small for induced fission and entirely absent for spontaneous fission). The default value, $c_{TS} = 1$, leads to $S_L \sim 6.2\hbar$ and $S_H \sim 7.6\hbar$ for $^{252}\text{Cf}(sf)$ and yields a reasonable agreement with the average energy of photons emitted in fission (see Ref. [20] for details).

After accounting for the total rotational energy of the two fragments, $E_{rot}$, we are left with a total of

$$E_{stat} = E_{sc}^* - E_{rot}$$

(10)

for statistical fragment excitation. It is distributed between the two fragments as follows.

First a preliminary partition, $E_{stat} = E_{L}^* + E_{H}^*$, is made according to the heat capacities of the two fragments which are assumed to be proportional to the corresponding Fermi-gas level density parameters, i.e.

$$\frac{E_{L}^*}{E_{H}^*} = \frac{a_L}{a_H},$$

(11)

where

$$a_i(E_i^*) = \frac{A_i}{e_0}\left[1 + \frac{\delta W_i}{U_i}(1 - e^{-\gamma U_i})\right],$$

(12)

with $U_i = E_i^* - \Delta_i$ and $\gamma = 0.05$/MeV [13, 29]. The pairing energy of the fragment, $\Delta_i$, and its shell correction, $\delta W_i$, are tabulated in Ref. [29] based on the mass formula of Koura [28]. The overall scale $e_0$ is taken as a model parameter but it should be noted that if the shell corrections are negligible, $\delta W_i \approx 0$, or the available energy, $U_i$, is large, then $a_i \approx A_i/e_0$, i.e. $a_i$ is simply proportional to the fragment mass number $A_i$, and this renormalization is immaterial. We currently assumes the universal value of 10.0724 MeV determined in Ref. [18] for $e_0$.

If the two fragments are in mutual thermal equilibrium, $T_L = T_H$, the total excitation energy will, on average, be partitioned as above. But because the observed neutron multiplicities suggest that the light fragments tend to be disproportionately excited, the average excitations are modified in favor of the light fragment,

$$E_L^* = xE_L^*, \quad E_H^* = E_{stat} - E_L^*,$$

(13)

where the adjustable model parameter $x$ is expected be larger than unity. It was found that $x = 1.3$ leads to reasonable agreement with $\nu(A)$ for $^{252}\text{Cf}(sf)$, while $x = 1.2$ is suitable for $^{235}\text{U}(n,f)$ [17].

After the mean fragment excitation energies have been assigned as described above, FREYA considers the effect of thermal fluctuations. In Weisskopf’s statistical model of the nucleus [30–32], which describes the excited nucleus as a degenerate Fermi gas, the mean excitation of a fragment is related to its temperature $T_i$ by

$$E_i^* = a_i(E_i^*)T_i^2$$

(14)

and the associated variance in the excitation is

$$\sigma_{E_i}^2 = -\frac{\partial^2 \ln \rho_i(E_i^*)}{\partial E_i^2} = 2E_i^*T_i.$$
Therefore, for each of the two fragments, we sample an energy fluctuation $\delta E^*_i$ from a normal distribution of variance

$$c^2 \sigma^2_{E_i} = c^2 E^*_i T_i.$$  

and adjust the fragment excitations accordingly, arriving at

$$E^*_i = E^*_i + \delta E^*_i, \quad i = L, H.$$  \hspace{1cm} (17)

The factor $c$ multiplying the variance was introduced to explore the effect of the truncation of the normal distribution at the maximum available excitation. It can be adjusted for each fissile nucleus\(^3\). Its value affects the neutron multiplicity distribution $P(\nu)$; previous work used the default value, $c = 1.0$.

Energy conservation is accounted for by making a compensating opposite fluctuation in the total kinetic energy [18].

$$\text{TKE} = \text{TKE} - \delta E^*_L - \delta E^*_H.$$  \hspace{1cm} (18)

2.3 Post-fission radiation

After their formation, FREYA assumes that the fully accelerated fission fragments first de-excite by sequential neutron evaporation (see Fig. 7), followed by sequential photon emission (see Fig. 8).

2.3.1 Neutron evaporation

Neutron evaporation occurs after the fragments have reached their asymptotic velocities. We treat postfission neutron radiation by iterating a simple treatment of single neutron evaporation until no further neutron emission is energetically possible.

Figure 7: Neutron evaporation.

A fission fragment is an excited nucleus with a total mass equal to its ground-state mass plus its excitation energy, $M^*_f = M^\text{gs}_f + E^*_f$. The $Q$ value for neutron emission is then

$$Q_n = M^*_f - M^\text{gs}_d - m_n$$

$$= M^\text{gs}_f + E^*_f - M^\text{gs}_d - m_n$$  \hspace{1cm} (19)

\(^3\)See footnote 1.
where $M^{gs}_{d}$ is the ground-state mass of the daughter nucleus, and $m_n$ is the mass of the ejectile. Using the definition for the neutron separation energy $S_n(Z,A) = -M(A-Z) + M(A-1)Z + m_n$, we have

$$Q_n = E_f^* - S_n(Z,A).$$  

(20)

The $Q$ value equals the maximum possible excitation energy of the daughter nucleus $Q_n = E^{\text{max}}_f$ for vanishing final relative kinetic energy of the ejectile, or when the emitted neutron has no kinetic energy.

Once the $Q$ value is known, it is straightforward to sample the kinetic energy of an evaporated neutron. The evaporated neutrons are assumed to be isotropic (in the frame of the emitting nucleus), apart from a very slight flattening due to the nuclear rotation. Their energy is sampled from a black-body spectrum,

$$\frac{dN_n}{dE_n} \sim E_n \exp\left(-\frac{E_n}{T_{\text{max}}}\right),$$  

(21)

where $T_{\text{max}}$ is the maximum possible temperature in the daughter nucleus (corresponding to emission of a very soft neutron) and is obtained from

$$a_d T_{\text{max}}^2 = Q_n,$$  

(22)

where $a_d$ is the level-density parameter of the daughter nucleus.

The excitation energy of the daughter nucleus is then given by

$$E^*_d = Q_n - E_n.$$  

(23)

FREYA generally assumes that neutron evaporation continues until the nuclear excitation energy is below the threshold $S_n + Q_{\text{min}}$, where $S_n$ is the neutron separation energy and $Q_{\text{min}} = 0.01$ MeV. Neutron evaporation continues as long as energetically possible. Afterwards, photon emission takes over.

### 2.3.2 Photon emission

After neutron evaporation has ceased, the excited product nucleus will undergo sequential photon emission which is treated in several stages. The most recent refinement uses the RIPL-3 data library [33] for the discrete decays towards the end of the decay chain [34].

![Figure 8: Photon emission.](image)  

The first stage is statistical radiation. These photons are emitted isotropically in the frame of the emitter nucleus with an energy that has been sampled from a black-body spectrum modulated by a GDR form factor,

$$\frac{dN_\gamma}{dE_\gamma} \sim \frac{\Gamma_{\text{GDR}}^2 E^2_\gamma}{(E^2_\gamma - E_{GDR}^2)^2 - \Gamma_{\text{GDR}}^2 E^4_\gamma} E^2_\gamma e^{-E_\gamma/T},$$  

(24)
where $T$, the nuclear temperature prior to emission, is equal to the maximum possible temperature after emission. The position of the resonance is taken as $E_{GDR}/\text{MeV} = 31.2/A^{1/3} + 20.6/A^{1/6}$ [35], while its width is $\Gamma_{GDR} = 5\text{MeV}$. It is assumed that each emission reduces the magnitude of the angular momentum by $dS$, the standard value being $dS = 1\hbar$.

This cascade is continued until the statistical excitation is below a specified threshold, $g_{\text{min}}$\textsuperscript{4}, which is usually taken to be $g_{\text{min}} = 100\text{keV}$. At this point the nucleus is near its yrast line, i.e., it is cold and rotating, and the remaining deexcitation occurs by emission of ‘collective’ photons that each reduce the angular momentum by $2\hbar$.

The RIPL-3 library [33] tabulates a large number of discrete electromagnetic transitions for nuclei throughout the nuclear chart, but complete information is available for only relatively few of them. However, by invoking certain assumptions (see Ref. [34]), it is possible to construct, for each product species, a table of the possible decays from the lowest discrete levels, i.e., the level energies $\{\varepsilon_{f}\}$, their half-lives $\{t_{f}\}$, and the branching ratios of their various decays. Then whenever the decay process described above leads to an excitation below any of the tabulated levels, FREYA switches to a discrete cascade based on the RIPL-3 data. The discrete cascade is continued until the half-life $t_{f}$ exceeds the specified value of $t_{\text{max}} = 1.5\text{ns}$. When comparing with experimental data, this FREYA parameter should be adjusted to reflect the response time of the detection system.

## 3 FREYA data files

The data files shown in this section are for the most part organized in order of use in the general FREYA sequence of events. Table 1 lists the files used by FREYA.

Upon startup, FREYA reads in a master data file containing

1. the ZA of the available compound nuclei before fission. There are currently 12 fissionable isotopes: 6 spontaneously fissioning ($^{235}\text{U}$, $^{238}\text{Pu}$, $^{240}\text{Pu}$, $^{242}\text{Pu}$, $^{244}\text{Cm}$, $^{252}\text{Cf}$) and 5 neutron-induced ($^{233}\text{U}$, $^{235}\text{U}$, $^{238}\text{U}$, $^{239}\text{Pu}$, $^{241}\text{Pu}$);

2. the maximum number of pre-fission neutrons in pre-fission neutron evaporation;

3. the names of the FREYA data files containing:
   (a) the probability distributions of mass partition $P(A_f)$;
   (b) the pre-equilibrium emission probabilities;
   (c) the pre-equilibrium emission spectra;
   (d) the kinetic energy distributions of the fission fragments.

Because additional isotopes are expected to be regularly added in the future, the code was designed to ease the extension to additional isotopes: algorithm and data are completely separated and isotopes can easily be added by adding lines to the master data file, and generating some of the required files 3a through 3d listed in the enumeration above.

### 3.1 Master data file react.dat

The master file ‘react.dat’ contains all of the data files that FREYA uses. It is thus shown in Figs. 1-8. The current version of this file is reproduced below:

\textsuperscript{4}See footnote 1.
Table 1: List of all data files needed by FREYA and the section of the text where they are described. The label isotope is a placeholder for the exact compound isotope (just before fission) included, e.g. U236 for the reaction $^{235}\text{U}(n,f)$.

If this file does not exist, the FREYA fission sampler outputs an error and returns.

Each line in this file corresponds to a compound isotope before fission. Except for the first header line, the overall structure of the master data file is described in Table 2. For neutron-induced fission, one should point out that ‘$A$’ is the number of nucleons in the compound nucleus, i.e. the nuclear mass number after the incident neutron has been captured by the fissile isotope. Thus the first line corresponds to the neutron-induced fission reaction $n+^{233}\text{U}$.

If a filename specified in ‘react.dat’ does not exist, FREYA outputs an error and returns. When a hyphen ‘-' replaces a filename, FREYA uses a default treatment, as described later.

3.2 Neutron separation energy in file SEPn.dat

As explained in Sec. 2, the neutron separation energy is used for multiple purposes. It is used to calculate the excitation energy of the nucleus after absorption of the incident neutron (see Fig. 1) for neutron-induced fission. It determines whether pre-fission evaporation (see Fig. 2) is possible: as long as the excitation energy of the compound nucleus exceeds the neutron separation energy $S_n$, one or more neutrons can be emitted before fission. It is used to determine the kinetic energy of the evaporation neutrons (see Fig. 7). For a fragment of statistical excitation $E^*$, the maximum temperature in its evaporation daughter, $T_{max}$, is obtained from $aT_{max}^2 = E^* - S_n(Z,A)$. The neutron kinetic energy $E_n$ is sampled from $f_n(E_n) \sim E_n \exp(-E_n/T_{max})$. Finally, it is used to calculate how many prompt neutrons are emitted by the fission fragments. Neutron evaporation ceases when the statistical excitation energy $E^* < S_n(Z,A) + Q_{min}$, i.e. neutrons are emitted as long as the $Q$ value for emission exceeds $Q_{min}$, at which point photon emission takes over.

This file contains the neutron separation energy for different fissile isotopes and is used to decide whether pre-fission neutron evaporation takes place. An excerpt of the data file “SEPn.dat” is shown below:

3.3 Data file fisbar.dat

The data file “fisbar.dat” is used in Fig. 2 showing pre-fission evaporation, and contains fission barriers of nuclei. The role of fission barriers is explained in Sec. 2.1.2. If a nucleus is not in the table, a default fission barrier of 0 MeV is used.

Fission barriers are used to compute the decay width of fission. The criterion for pre-fission evaporation is not whether it is energetically possible \((E^* > S_n)\), as in neutron evaporation explained in Sec. 2.3.1. Rather, a choice is made based on \(\Gamma_n(E^*)/\Gamma_f(E^*)\), the relative magnitudes of the decay widths. Of course, \(\Gamma_n(E^*)\) vanishes for \(E^*\) below \(S_n\).

An excerpt of data file “fisbar.dat” is shown below:

<table>

3.4 Data file acorrection.dat

Similarly to data file ‘fisbar.dat’, “acorrection.dat” is used in Fig. 2 for pre-fission evaporation and contains correction factors for the level-density parameters of a few isotopes of uranium and plutonium.

As is common, FREYA assumes nuclei level densities to be of the form \(\rho(E_i^*) \sim \exp(2\sqrt{a_i U_i})\), where \(U_i\) is the effective statistical energy and \(a_i\) is the level-density parameter. Level-density parameters enter in the calculation of \(\Gamma_n(E_i^*)\) and \(\Gamma_f(E_i^*)\), the neutron evaporation and fission decay widths [22]. For a few isotopes of uranium and plutonium, the level-density parameters \(a_i\) are multiplied by correction factors \(a_n\) and \(a_f\) for these calculations.

The data file “acorrection.dat” is reproduced below in its entirety:

<table>
<thead>

3.5 Data files associated with pre-equilibrium neutron emission

In pre-equilibrium neutron emission, an incident neutron interacts with the fissile nucleus and is re-emitted afterwards before the nucleus fissions. It is different from multichance fission, where a neutron other than the incident neutron is emitted before fission. Files with pre-equilibrium emission probabilities and pre-equilibrium energy spectra are used in the algorithm for pre-equilibrium neutron emission, see Fig. 1.

In file ‘react.dat’ ²³⁴U*, ²³⁶U*, ²³⁹U*, ²⁴⁰Pu* and ²⁴²Pu* have pre-equilibrium emission probabilities and energy spectra. For a given isotope, both the pre-equilibrium emission probability and the energy spectrum are necessary. If one is given and the other is missing, the FREYA fission sampler will return with an error message.

3.5.1 Pre-equilibrium emission probabilities

The excerpt of file ‘U236.xs’ below shows the probability of pre-equilibrium neutron emission from the compound nucleus ²³⁶U as a function of the incident neutron energy $E_{in}$:

U-236.xs: Probability for pre-equil emission vs Ein:
100 0.20000
  0 0.00000 0.00000000E+00
  1 0.20000 0.00000000E+00
  2 0.40000 0.00000000E+00
  3 0.60000 0.00000000E+00
  4 0.80000 0.00000000E+00
  5 1.00000 0.6432276E-04
  6 1.20000 0.2734767E-03
  7 1.40000 0.6399593E-03
(...)
  99 19.80000 0.2314241E+00
 100 20.00000 0.2336182E+00

The overall structure of the data file, from line 3 on, is described in Table 6. The first two lines are header lines. Line 1 is an identifying comment. Line 2 has two entries: a) The total number of data entries in the file “minus one”. (In this case, the file has 101 data entries; thus the first number on line 2 is 100); b) The width of the energy bins in units of MeV. (The bin width is 0.2 MeV in this file.)

For the compound nucleus ²³⁶U, we read in file “U236.xs” that the probability for pre-equilibrium neutron emission is null for neutron incident energies from 0 to 0.8 MeV.

3.5.2 Pre-equilibrium emission spectra

An example of the neutron spectrum from pre-equilibrium emission is shown below as a function of $E_{in}$. These lines are taken from file ‘U236.PreEq’ for the compound nucleus ²³⁶U:
Table 6: Structure of pre-equilibrium emission probability data file

0.911493 0.4754821E-02
1.062331 0.1891974E-02
```

Except for the first two header lines, the overall structure of the data file for the pre-equilibrium neutron emission spectrum is explained in Tables 7 and 8. The structure description in Table 7 applies to lines 3-8, 10, 13, etc. of file “U236.PreEq” shown above. For the other lines, the structure description in Table 8 applies.

Table 7: Structure of pre-equilibrium emission spectrum data file

<table>
<thead>
<tr>
<th>Column</th>

<td>Number of entries in the pre-equilibrium neutron energy spectrum</td>
</tr>
<tr>
<td>4</td>
<td>Bin width of the pre-equilibrium energy spectrum in units of MeV. (Identical for all entries.)</td>
</tr>
</tbody>
</table>

The file “U236.PreEq” gives the emission spectrum out to its kinematic endpoint. The entry numbers and incident neutron energies are the same as those in the first two columns of the probability distribution, as described in Table 7. If the third entry in “U236.PreEq” is 0, there are no emission spectrum entries since there
is zero probability for emission. If this entry is nonzero, the emission spectrum follows with a number of entries equal to the integer value of Column 3. Table 8 describes these entries.

Table 8: Description of pre-equilibrium emission spectrum for each incident neutron energy where the number of entries in the third column of Table 7 is not null.

The number of data points and the width of the incident neutron energy bins in the pre-equilibrium emission probability and the energy spectrum files must match.

### 3.6 Data file Zdis.dat

The data file ‘Zdis.dat’ is used to sample the fission fragment charge partition, see Fig. 3. It contains the standard deviation $\sigma_Z$ in Eq. (3) for few elements with $220 \leq A \leq 260$. An excerpt of the file is shown below:

```
A charge distribution
220 0.38
221 0.38
(...)
259 0.47
260 0.47
```

The overall structure of the data file ‘Zdis.dat’, aside from the first header line, is explained in Table 9.

### 3.7 Data files for fission fragment yields

In cases where either data on only a single incident energy is available or for some spontaneously fissioning isotopes, the fragment yields are sampled from a single data file. The structure of these data files are described in Sec. 3.7.1. In other cases, a five-Gaussian fit to the fragment yields has been made. The structure of the data file containing the fit parameters, ‘gaussfit.dat’, is described in Sec. 3.7.2. (Both single data files and five-Gaussian fits are available for spontaneous fission. In general the data file is used for sampling in these cases.) When the full incident neutron energy dependence of the yields is required for energies up to $E_n = 20$ MeV, an energy dependence of the Gaussian fits has been developed, as discussed in Sec. 3.7.2.
3.7.1 Data files for single fission fragment yields $P(A_f)$

The data files for single energy or spontaneous fission fragment yields $P(A_f)$ are used in the selection of the fission fragment mass numbers, see Fig. 3. The excerpt of the file ‘U238sf.Y-Af’ below shows $P(A_f)$ for spontaneous fission of the nucleus $^{238}_{\text{U}}$ in ‘react.dat’.

$P(A_f)$ for $^{238}_{\text{U}}$ (sf) [Ivanov, INT]

<table>
<thead>
<tr>
<th>A_f</th>
<th>P(A_f)</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>157</td>
<td>0.0513</td>
</tr>
<tr>
<td>0</td>
<td>0.00</td>
</tr>
</tbody>
</table>

Aside from the first header line, the lines of the $P(A_f)$ files are described in Table 10. The fragment yields

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Fragment mass number, $A_f$</td>
</tr>
<tr>
<td>2</td>
<td>Fragment yields $P(A_f)$</td>
</tr>
<tr>
<td>3</td>
<td>Uncertainty on $P(A_f)$, when available</td>
</tr>
</tbody>
</table>

$P(A_f)$ do not need to be normalized, the code normalizes them automatically. The header line indicates the origin or author of the data, e.g. “Ivanov”. The end of the data file is identified by a line where the fragment mass number $A_f$ is 0.

3.7.2 Data file gaussfit.dat

When the file name for the fission fragment yield $P(A_f)$ is replaced by a hyphen ‘-‘ (e.g. $^{230}_{\text{U}}^*$ and $^{240}_{\text{Pu}}^*$ in file ‘react.dat’), FREYA samples the fission products from a five-Gaussian fit to the fission product yield distributions. The fits are isotope and energy dependent, as is now described.

The mass yields $Y(A_f)$ of the fission fragments for a given neutron energy $E_n$ are composed of three distinct Gaussian modes,

$$Y(A_f) = G_1(A_f) + G_2(A_f) + G_0(A_f).$$  \hspace{1cm} (25)$$

The first two terms represent asymmetric fission modes associated with the spherical shell closure at $N = 82$ and the deformed shell closure at $N = 88$, respectively. The last term is a symmetric mode. While this mode is small at low excitation energies, its importance increases with excitation energy.

The asymmetric modes are composed of two Gaussians,

$$G_i = \frac{C_{ni}}{\sqrt{2\pi}W_{ni}} \left[ \exp \left( -\frac{(A_f - \overline{A} - D_{ni})^2}{2W^2_{ni}} \right) + \exp \left( -\frac{(A_f - \overline{A} + D_{ni})^2}{2W^2_{ni}} \right) \right],$$  \hspace{1cm} (26)$$

where $i = 1, 2$ while the symmetric mode is given by a single Gaussian

$$G_0 = \frac{C_{n0}}{\sqrt{2\pi}W_{n0}} \exp \left( -\frac{(A_f - \overline{A})^2}{2W^2_{n0}} \right),$$  \hspace{1cm} (27)$$

with $\overline{A} = A_0/2$. 

21 LLNL-SM-705798
The values of $D_{ni}$ are displacements that are anchored above the symmetry point by the spherical and deformed shell closures. Because these occur at specific neutron numbers, $D_{ni}(i)$ are energy independent. The values of $D_{ni}(i)$ are smaller for $^{240}$Pu* than $^{236}$U* due to the larger value of $A_0$ for Pu.

The widths of the asymmetric Gaussians are assumed to be energy dependent and are expended to second order in neutron energy,

$$W_{ni} = W_n(i, 0) + W_n(i, 1)E_n + W_n(i, 2)E_n^2.$$  \hspace{1cm} (28)

The width of the symmetric Gaussian is assumed to be energy independent.

The energy dependence of the normalization coefficients $C_{n1}$ and $C_{n2}$ is given as

$$C_{ni} = C_n(i, 0) \left(1 + \exp\left[\left(E_n - C_n(i, 1)/C_n(i, 2)\right)\right]\right)^{-1}.$$  \hspace{1cm} (29)

Since each event leads to two fragments, the yields are normalized so that $\sum_{A_f} Y(A_f) = 2$. Thus,

$$2C_{n1} + 2C_{n2} + C_{n0} = 2,$$  \hspace{1cm} (30)

apart from a negligible correction because $A_f$ is discrete and bounded from both below and above. Therefore, $C_{n0}$ is determined from Eq. (30) at each value of $E_n$.

Finally, we note that, above the threshold for pre-fission neutron evaporation, the yields include contributions from first-chance fission and higher. For more information, see Ref. [18].

The list of parameters used for the gaussian fits are in the file ‘gaussfit.dat’, reproduced below. The structure of ‘gaussfit.dat’ is described in Table 11.

3.8 Isotopic mass tables

The isotope mass tables used in the scission algorithm in Fig. 4 are described here. When available, the experimental measurements in ‘MassAudi.dat’ are used. Otherwise, the theoretical values in ‘MassMNMS.dat’ are
used.

The structure of the two files is essentially identical. Both files have a five-line header, including two
equations, identifying the components of the file. The first equation of the five-line header gives the ground
state mass of the nucleus,

\[ M(Z,A) = Au + D(Z,A) , \]  

(31)

where \(Au\) is the mass number times the atomic mass unit, and \(D(Z,A)\) is the mass defect, all in units of MeV.
The numerical value for \(u\) is given in the third line of the header file, also in units of MeV. The second equation,
on the fourth line of the header, defines the nuclear binding energy

\[ B(Z,A) = ZD(H) + ND(n) - D(Z,A) . \]  

(32)

The binding energy of the compound nucleus is the difference between the sum of the mass defects for all
nucleons and the mass defect of the compound nucleus.

The structure of the data in these files following the header is explained in Table 12. To indicate the end of
the data files, the last line of the file has five zero values.

3.8.1 Theoretical isotopic mass tables in data file MassMNMS.dat

The theoretical isotopic masses, mass defects and binding energies are taken from Möller et al. [26]. The
excerpt from the file ‘MassMNMS.dat’ shows some of the theoretical masses. Note that the lowest tabulated
theoretical mass is for \(^{16}\text{O}\), \(Z = 8, A = 16\).

* Theoretical masses from MNMS 1995:
  * \(M(Z,A) [\text{MeV}] = A*u + D(Z,A)\) where \(u\) is
    931.493835 MeV
  * \(B(Z,A) = Z* D(H) + N* D(n) - D(Z,A)\)

<table>

3.8.2 Experimental isotopic mass tables in data file MassAudi.dat

This table contains the experimentally measured isotopic masses, mass defects and binding energies published
by Audi and Wapstra [25]. Whenever available, the experimental values will override the theoretical ones in
Sec. 3.8.1. An excerpt of this file is shown below. Note that the neutron \((Z = 0, A = 1)\) and proton \((Z = 1, A = 1)\) are the first two entries in this table.

* Audi & Wapstra NPA595 (1995) 409:
* \(M(Z,A) [\text{MeV}] = A \times u + D(Z,A)\) where \(u\) is 
  931.493835 MeV
* \(B(Z,A) = Z \times D(H) + N \times D(n) - D(Z,A)\)

3.9 Total kinetic energy data file

FREYA needs to read in the total kinetic energy TKE data files, given as a function of the heavy fragment mass \(A_H\). One or more TKE files per isotope are allowed. The number of TKE files for a given isotope is specified in the field ‘# TKE files’ in ‘react.dat’. When multiple TKE files are entered, the code calculates the average of the experimental TKE values for each \(A_H\), counting each data point equally. (Therefore \(A_H\) and \(A_L = A_0 - A_f\) count equally). An entry of 0 in the field ‘# TKE files’ is invalid because there is no default behavior for the total kinetic energy data. If the TKE data file is missing or invalid, FREYA will generate an error message.

The total kinetic energy data files are used in the algorithm for the selection of fission fragment energies, see Fig. 5 and Eq. 5. An example of a TKE file is shown below for neutron-induced fission of \(^{235}\text{U}\), for the compound nucleus \(^{236}\text{U}^*\):

\[
\text{TKE}(A_f) \text{ for } ^{236}\text{U}(n,f) \text{ [Nishio]:}
\]

78 158
78 148.0319
79 149.8098
(...)
157 149.8098
158 148.0319

The first line indicates the compound nucleus and the origin or author of the data, e.g. “Nishio”.

3.10 Data file inputparameters.dat

FREYA contains a number of adjustable parameters that control various physics aspects. File ‘inputparameters.dat’ contains the parameters used to calculate the total excitation energy of the fission fragments and partition the excitation energy between the two fragments (see Eqs. (5)-(16) in Sec. 2). This file enters into the algorithm for the selection of fission fragment energies (Figs. 5-6) and the algorithm for the neutron evaporation and photon emission (Figs. 7-8).
This file also includes the parameter $dTKE$ which shifts the TKE globally to get agreement with the measured average neutron multiplicity, $\bar{\nu}$. If a hyphen '-' is given in the field 'dTKE file name' or if this field is empty, FREYA uses the energy-independent value specified in the next field 'dTKE'. An entry in the column 'dTKE file name' is only expected for neutron-induced fission at multiple energies, for $E_n$ up to 20 MeV.

If isotopes in file ‘react.dat’ have no entries in file ‘inputparameters.dat’, the unspecified fields take the species-independent default values listed in Table 14.

26 LLNL-SM-705798
3.11 Data file `alevel.dat`

The file `alevel.dat` contains the values δW and Δ in Eq. (12) which are used to include shell corrections and pairing effects in the level-density parameter ai (see function `alevel` in FORTRAN code). The data in this file enter whenever the level density is used, not only when dividing the statistical excitation between the two fragments but also when sampling the energy of an emitted neutron or photon. The flow charts indicate that `alevel.dat` is used to determine fission fragment rotational energies and thermal fluctuations (see Figs. 5-6) as well as for neutron evaporation and photon emission (Figs. 7-8). An excerpt of file `alevel.dat` is shown below.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

01dec09 (JR):: Entries added for Z=19 & 94 which are needed for 239Pu(n,f); the shell energy deltaW was taken as Emic from MNMS, while the pairing energy Delta was extrapolated from nearby values already in the table.

* Remember to increase the parameter 'max' in alevel when augmenting the table.

Aside from the first header line and the last comment lines, the overall structure of the data in this file is described in Table 15. The data file `alevel.dat` must contain values of Z, A, δW, Δ in order of uninterrupted, increasing Z. The values for each Z in order of uninterrupted, increasing A are nested within the increasing Z values. Of the 7090 current entries, 7050 entries are from Koura [28]. Twenty-six entries for Z = 18 (8), Z = 19 (7) and Z = 94 (11) were added for 239Pu(n,f). For these extra entries, the shell energy δW was taken to be Emic, the microscopic (pairing and shell) part of the nuclear potential energy of deformation, from Ref. [26], while the pairing energy Δ was extrapolated from nearby values already in the table. Five entries were added for Z = 96 and seven entries for Z = 98. For these twelve entries, zeros were used for δW and Δ because the values are not experimentally accessible and there is no need for refined values. Finally, δW and Δ values were added for 241Pu and 242Pu. The line following the last data line is identified by at least four numbers, the first one of which must be Z = 0.

### Table 15: Description of structure for data file `alevel.dat`

<table>
<thead>

Beware that the maximum number of entries in that file is currently set to 7090.
3.12 Data files for RIPL-3 photon decays

The RIPL-3 [33] photon decay levels have been added to FREYA. The RIPL-3 libraries have been modified for fast searches to suit FREYA’s needs. The data files needed for implementation of these libraries are discussed in this subsection.

3.12.1 Data file nA.dat

The data file nA.dat lists the number of isotopes (i.e. A values) for each element (i.e. Z value) included from the RIPL-3 tables. The first several and the last few lines of nA.dat are shown below:

\[
nA(Z): \text{Number of isotopes for each } Z
\]

\[
8 \quad 80: \text{minZ & maxZ}
\]

\[
8 \quad 6
9 \quad 7
10 \quad 6
11 \quad 7
12 \quad 8
13 \quad 7
14 \quad 7
15 \quad 7
16 \quad 7
17 \quad 9
18 \quad 9
19 \quad 9
20 \quad 13
(\ldots)
79 \quad 16
80 \quad 23
\]

The first line is a descriptor: \(nA(Z)\) is the number of isotopes included for an element with charge \(Z\). The second line gives the minimum and maximum values of \(Z\) for the elements included. The remainder of the data file nA.dat lists the number of isotopes included for each element (see Table 16).

<table>
<thead>
<tr>
<th>column</th>
<th>notation</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(Z)</td>
<td>Nuclear charge number (Z)</td>
</tr>
<tr>
<td>2</td>
<td>(nA)</td>
<td>Number of mass numbers (A) for this (Z)</td>
</tr>
</tbody>
</table>

3.12.2 Data file iAZ.dat

The data file iAZ.dat gives the mass number \(A\) of isotope \(\#m\) for element \(Z\). The first several and the last few lines of iAZ.dat are shown below:

\[
iAZ(Z,m): \text{Mass numbers for each } Z
\]

\[
8 \quad 80: \text{minZ & maxZ}
8 \quad 1 \quad 15
8 \quad 2 \quad 16
8 \quad 3 \quad 17
8 \quad 4 \quad 18
8 \quad 5 \quad 19
8 \quad 6 \quad 20
\]
The first line is a descriptor: \( iAZ(Z,m) \) is the mass number of included isotope number \( m \) for the element with charge number \( Z \). The second line gives the minimum and maximum values of \( Z \) for the elements included. The remainder of the data file \( iAZ.dat \) lists the mass numbers for each included nuclide (see Table 17). For a given \( Z \), the first (and smallest) included \( A \) value is \( A_{\text{min}}(Z) = iAZ(Z,1) \) and the last (and largest) included \( A \) value is \( A_{\text{max}}(Z) = iAZ(Z,nA(Z)) \). But not all the intermediate \( A \) values are necessarily included, isotopes that have no excited levels contribute no decay lines and are omitted (such passive isotopes have index zero, see Sec. 3.12.3 below).

Table 17: Description of the data on the file \( iAZ.dat \)

<table>
<thead>
<tr>
<th>column</th>
<th>notation</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>( Z )</td>
<td>Nuclear charge number ( Z )</td>
</tr>
<tr>
<td>2</td>
<td>( m )</td>
<td>Number of included isotope for this ( Z ) ((m=1,\ldots,nA(Z)))</td>
</tr>
<tr>
<td>3</td>
<td>( A )</td>
<td>Mass number ( A ) for included isotope ( #m ) of element ( Z )</td>
</tr>
</tbody>
</table>

3.12.3 Data file \( nAZ.dat \)

The data file \( nAZ.dat \) gives the sequential index \( N(Z,A) \) for each included nuclide with mass number \( A \) and charge number \( Z \) for the elements included. The first several and the last few lines of \( nAZ.dat \) are shown below:

Index for nucleus \((Z,A)\)

| 8  | 80: minZ & maxZ |
| 8  | 1 1 |
| 8  | 2 2 |
| 8  | 3 3 |
| 8  | 4 4 |
| 8  | 5 5 |
| 8  | 6 6 |
| 9  | 1 7 |
| 9  | 2 8 |
| 9  | 3 9 |
| 9  | 4 10 |
| 9  | 5 11 |
| 9  | 6 12 |
| 9  | 7 13 |
| 10 | 1 14 |

(...)

| 80 | 25 1196 |
| 80 | 26 1197 |
The first line is a descriptor: this file defines the index $N(Z,A)$ for each included nuclide $^A Z$. The second line gives the minimum and maximum values of $Z$ for the elements included. The remainder of the data file nAZ.dat lists the global index for each considered nuclide (see Table 18). The included nuclides are indexed sequentially, with the first being $N(8,15) = 1$ and the last being $N(80,205) = 1197$. Thus the nuclide $^A Z$ has the index $N(Z,A) = nAZ(i,j)$ with $i = Z$ and $1 \leq j \leq A_{\text{max}}(Z) - A_{\text{min}}(Z) + 1$ with $A_{\text{min}}(Z) = iAZ(1)$ and $A_{\text{max}}(Z) = iAZ(nA(Z))$. Note that $A_{\text{max}}(Z) - A_{\text{min}}(Z) + 1$ may exceed $nA(Z)$ because a nuclide $^A Z$ for which only the ground state is in the RIPL-3 table contributes no photon lines and is omitted, with the corresponding index $N(Z,A)$ being set to zero. [The first such example occurs for $^{35}P$ which has $i=15$ and $j=7$.]

### Table 18: Description of the data on the file nAZ.dat

<table>
<thead>
<tr>

<td>Index for the nuclide $^A Z$</td>
</tr>
</tbody>
</table>

3.12.4 Data file nl.dat

The data file nl.dat gives the number of energy levels included for each of the included nuclides (i.e. those whose index is positive). The first several and the last few lines of nl.dat are shown below:

nl(N): Number of energy levels in nucleus #N
1197: Number of Nuclei

<table>
<thead>
<tr>
<th>44</th>
<th>1</th>
<th>8</th>
<th>15</th>
</tr>

<td>80</td>
<td>204</td>
</tr>
<tr>
<td>9</td>
<td>1197</td>
<td>80</td>
<td>205</td>
</tr>
</tbody>
</table>

The first line is a descriptor: this file gives the number of energy levels included for nucleus #N. The second line indicates the total number of included nuclides (i.e. those having photon lines). The remainder of the data file nl.dat lists the number of levels for each included nuclide (see Table 19). The data nl.dat file does not include nuclides for cases where only ground state nuclei are included in the RIPL-3 table (so, occasionally, for a given $Z$, the mass number $A$ is not sequential).
Table 19: Description of the data on the file nl.dat

\end{array}
\]

1196 35485
1197 35494

The first line is a descriptor: the array \( lN(N) \) points to the location of the last level of each included nuclide, starting with \( lN(0)=0 \) and \( lN(1)=nl(1) \); generally we have \( lN(N)=lN(N-1)+nl(N) \). There are a total of 35494 contributing levels (last line).

</table>

The first line is a descriptor of the three characteristics of a level (N,ℓ): its excitation energy, E(N,ℓ), the number of possible decays from that level, nγ(N,ℓ), and the associated half-life, t(N,ℓ). Thus the number of lines in Ek.dat following line 2 is the number of included levels, 35494.

<table>
<thead>

<td>location of last decay from the level;</td>
</tr>
<tr>
<td>5</td>
<td>t(N,ℓ)</td>
<td>half-life of the level (seconds)</td>
</tr>
</tbody>
</table>

The RIPL-3 levels that are included in the tables have been renumbered as necessary to ensure that they appear according to increasing energy. Because the energy is given relative to the ground state, the first tabulated level for each nuclide is always zero. In any given nuclide, some levels may have the same energy, but they will generally not have the same half-life.

Each included level (N,ℓ) has nγ(N,ℓ) possible decays identified by k = 1, nγ, except for the ground state which has nγ(N,1) = 0. The information on these decays, the final levels and the branching ratios, is stored sequentially into a combined arrays and k(N,ℓ) points to the location of the last decay from the level ℓ in the nuclide #N. Thus the value of k(N,ℓ) for the last decay branch from the highest included level ℓ in the last included nuclide #N equals the total number of different decays included, 266950.

The half-life of a level is given, if known. If not, it is given as zero in the data file, while a negative value, -1, indicates that the level is stable.

3.12.7 Data file Fij.dat

The data file Fij.dat provides the information needed for FREYA to make the selection between the different competing decay branches during the final cascade through the discrete levels.

The beginning of Fij.dat is shown below:
nf & Fij:

and annotated excerpts of its bulk part (following the two initial lines) are shown in Fig. 9.

![Figure 9: Annotated excerpt of the data file Fij.dat.](image)

Figure 9: Annotated excerpt of the data file Fij.dat.
After the descriptive headline follows a line giving the total number of decays included. Then follows the bulk of the file which is nested according to the nuclide considered, \#N, its levels, \( \ell = 1, n_\ell(N) \), and the decays from those levels, \( k = 1, n_\gamma(N, \ell) \). (In the annotations, \( n_\ell \) is denoted as N\_\ell and \( n_\gamma \) as N\_\gamma.)

At the top level there is an introductory line giving the global index of the nuclide, \#N, the cumulative number of levels (denoted by \( n_0 \)) which is zero for the first nuclide, and the number of contributing levels \( n_\ell \) (indicated as N\_\ell), the number of decays from that particular level. The ground state corresponds to \( \ell = 1 \) and has no decays, \( n_\gamma(\ell = 1) = 0 \). We also note that the cumulative number of levels up to the last nuclide (\#N=1197) is \( n_0 = 35485 \), so that adding the number of levels associated with the last nuclide, \( n_\ell(1197) = 9 \), indeed yields the previously stated total number of levels, 35494.

Finally, at the innermost level, there is one line for each of the \( n_\gamma \) decays specifying the final level \( \ell_f \) (denoted as N\_\ell_f or simply \( f \) where space is tight) and the associated cumulative probability \( F_{ij}(k) \),

\[
F_{ij}(k) = \sum_{k'}^{k} P(\ell \rightarrow \ell_f(k')) ,
\]

where \( P(\ell_i \rightarrow \ell_f) \) denotes the branching ratio for the decay from the level \( \ell_i \) to the level \( \ell_f \). We note that \( F_{ij}(k) \) increases monotonically from the first (and largest) branching ratio \( P(\ell \rightarrow \ell_f(k = 1)) \) to unity as \( k \) is increased from one to \( n_\gamma \). The sampling of the decay branch \( k \) can therefore be made by generating a random number \( \eta \in [0,1) \) and determining the lowest value of \( k \) for which \( F_{ij}(k) \) exceeds \( \eta \).

Table 22: Description of structure for top level of data file ‘Fij.dat’

<table>
<thead>
<tr>
<th>column</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Index of isotope ((Z,A)), runs from 1 to 1197</td>

<td>Number of levels for given ((Z,A))</td>
</tr>
<tr>
<td>4</td>
<td>Proton number (Z)</td>
</tr>
<tr>
<td>5</td>
<td>Mass number (A)</td>
</tr>
<tr>
<td>6</td>
<td>‘====’ Separator</td>
</tr>
</tbody>
</table>

Note that for column 2 in the top level, for the first nucleus, the last level of the previous nucleus does not exist so it is given the value of zero for \((Z,A) = (8,15)\).

In the two upper levels of the data file Fij.dat, there is a ‘:’ placed as a separator between the level information and the \( Z \) and \( A \) of the isotope. There are also different separators ‘======' in the top level and ‘—’ in the second level to help guide the eye of anyone perusing the data file. They are not used but help make it more human readable.

The levels are arranged so that the lowest decay probability for a given level is first, highest last. This is not necessarily in the same order as in the original table. The data have been sorted for fastest searching. The decay probabilities are renormalized so that the probability for the last decay in the list is exactly unity.

The index for the daughter level in column 5 of the third level of file Fij.dat is not sequential and may seem incomplete. This index is taken from the RIPL-3 table. Note that in FREYA, only the probabilities for photon emission have been retained. The probabilities for decay by electromagnetic transitions are not kept because FREYA does not include these transitions. The coefficients for internal conversion are also not retained in Fij.dat.

4 Running FREYA

This section illustrates how to use FREYA within the LLNL Fission Library. Some short codes are presented, both employing application programmable interfaces (APIs). The first uses the C++ API, while the second uses the C API. They both create a histogram exhibiting the angular correlation between two neutrons emitted during fission.

4.1 Integration of FREYA in LLNL Fission Library

FREYA was first integrated into the LLNL Fission Library, which already provided an existing interface to MCNPX and MCNP6. Conveniently, no modification of MCNPX/MCNP6 was necessary after the LLNL Fission Library was substituted in the source code tree.

Currently, FREYA selects outgoing projectiles from spontaneous and neutron-induced fission for incident neutron energies below 20 MeV. Photofission is planned for the near future. For each spontaneous or neutron-induced fission event, the code checks whether the sampled isotope is available in FREYA. If present, FREYA is called to sample multiplicity, energy, and direction of the fission neutrons, all of which are passed back to the LLNL Fission Library and eventually to MCNP for transport. All other fission events are handled by the default LLNL Fission Library settings in the usual way. When in use, FREYA predicts a host of correlations between outgoing fission products: correlations in neutron multiplicity, energy and angles, and energy sharing between neutrons and photons.
4.2 Verification

We verified [36] that FREYA is yielding the correct average neutron induced fission spectrum within MCNP by calculating the criticality parameter \( k_{\text{eff}} \) for the critical assemblies Godiva and Jezebel [37]. The \( k_{\text{eff}} \) results using FREYA were 0.9994±0.0009 (Jezebel) and 1.0003±0.0008 (Godiva), in good agreement with the default MCNP values.

4.3 Setting up the environment

The LLNL Fission Library/FREYA package is available at the following URL: http://nuclear.llnl.gov/simulation/. The FREYA part of the package is written in Fortran 90 and has been tested with both gfortran and the Intel Fortran compiler. A standard Makefile builds the LLNL Fission Library/FREYA as a static library, which can then be linked in with host radiation transport codes.

In order to run, the environment variable FREYADATAPATH must point to the directory containing the data files used by FREYA. In the bash shell, this can be done with the following statement:

```bash
export FREYADATAPATH=/path/to/freya/data/directory/
```

If unspecified, the LLNL Fission Library will look into the directory “./data” to find the data for FREYA.

4.4 Error conditions and limitations

If a valid location for the data is not found, an error message will be generated and the LLNL Fission Library will run under correlation option 0 (see Sec. A.1.7), that is without FREYA turned on.

If a reaction (spontaneous fission or neutron-induced fission) for an isotope is not specified in the master data file “react.data”, an error message will be generated and the LLNL Fission Library will temporarily revert to correlation option 0 (see Sec. A.1.7) for this reaction. The same happens if the energy of an incident neutron is greater than 20 MeV or if one of the error conditions described in Sec. 3 occurs.

Error messages can be retrieved by the user, see Secs. A.1 and A.2.

4.5 Code using C++ API

This first code uses the C++ interface described in Sec. A.1 to invoke the LLNL Fission Library:

```cpp
#define iterations 3000000
#define nbins 100

#include <stdio.h>
#include "fissionEvent.h"

void init(void);
FILE* openfile(char* name);
void output(int* hist);

int main() {
    int isotope = 94239;
    double energy_MeV = 2.0;
    double nubar = 3.163;
    double time = 0.0;

    int maxerrorlength=10000;
    char errors[maxerrorlength];
    int hist[nbins];
```
for (int i=0; i<nbins; i++) hist[i] = 0.;

init();
for (int i=0; i<iterations; i++) {
    fissionEvent* fe = new fissionEvent(isotope, time, nubar, energy_MeV, 1);
    int errorlength=maxerrorlength;
    fe->getFREYAerrors(&errorlength, &errors[0]);
    if (errorlength>1) {
        printf("%s\n",errors);
        exit(1);
    }
    int nneutrons = fe->getNeutronNu();
    for(int n1=0; n1<nneutrons; n1++) {
        double u1 = fe->getNeutronDircosu(n1), v1 = fe->getNeutronDircosv(n1), w1 = fe->getNeutronDircosw(n1);
        for(int n2=n1+1; n2<nneutrons; n2++) {
            double u2 = fe->getNeutronDircosu(n2), v2 = fe->getNeutronDircosv(n2), w2 = fe->getNeutronDircosw(n2);
            double scalar_product = u1*u2+v1*v2+w1*w2;
            int bin_index = (int) (nbins*(scalar_product+1)/2);
            hist[bin_index]++;
        }
    }
    delete fe;
}
output(hist);

void init(void) {
    unsigned short int s[3] = {1234, 5678, 9012};
    int i;
    seed48(s);
    fissionEvent::setCorrelationOption(3);
    return;
}

FILE* openfile(char* name) {
    FILE* fp = fopen(name, "w");
    if (fp == (FILE *) 0) fprintf(stderr, "Could not open %s for writing", name);
    return fp;
}

void output(int* hist) {
    char filename [1024];
    sprintf(filename, "freya_correlations.res");
    FILE* fp = openfile(filename);
    unsigned int sum=0;
    for (int i=0; i<nbins; i++) sum += hist[i];
    for (int i=0; i<nbins; i++) fprintf(fp, "%e - %e : %e\n", -1+2.*i/nbins, -1+2.*(i+1)/nbins, 1.*hist[i]/sum);
    fclose(fp);
    return;
}

In the initialization phase, the random number generator is seeded, the call to fissionEvent::setCorrelationOption(3) turns on FREYA. A new instance of class fissionEvent is created for each new fission, from which we extract
the directions of the emitted neutrons. Potential error messages produced by FREYA can be retrieved by the programmer via a call to \texttt{fissionEvent::getFREYAerrors()}. An example of such error is failure to specify a valid location for FREYA’s data using \texttt{FREYADATAPATH}.

This code produces an output file with the distribution of angles between fission neutrons. This distribution is shown in Fig. 10.

![Figure 10: Distribution of angles between neutrons emitted by fission of $^{239}$Pu induced by 2 MeV neutrons.](image)

4.6 Code using C API

The same code can interface with the LLNL Fission Library using the C interface described in Sec. A.2:

```c
#include "Fission.h"

int main() {
    int isotope = 94239;
    double energy_MeV = 2.;
    double nubar = 3.163;
    double time = 0.;

    int i, hist[nbins];
    for (i=0; i<nbins; i++) hist[i] = 0.;

    init();
    for (i=0; i<iterations; i++) {
        genfissevt_(&isotope, &time, &nubar, &energy_MeV);
        int nneutrons = getnnu_();
        int n1;
        for(n1=0; n1<nneutrons; n1++) {
            double u1 = getndircosu_(&n1), v1 = getndircosv_(&n1), w1 = getndircosw_(&n1);
            int n2;
            for(n2=n1+1; n2<nneutrons; n2++) {
```

```c
```
double u2 = getndircosu_(&n2), v2 = getndircosv_(&n2), w2 = getndircosw_(&n2);
double scalar_product = u1*u2+v1*v2+w1*w2;

int bin_index = (int) (nbins*(scalar_product+1)/2);
hist[bin_index]++;
}
}
output(hist);

int errorlength=10000;
char errors[errorlength];
getfreya_errors_(&errorlength, &errors[0]);
if (errorlength>1) printf("%s\n",errors);

void init(void) {
  unsigned short int s[3] = {1234, 5678, 9012};
  int i, three = 3;
  seed48(s);
  setcorrel_(&three);
  return;
}

Some sections from this code were removed because they are identical to those presented in Sec. 4.5.

5 Conclusion

This manual describes the event-by-event fission generator FREYA and its integration into the LLNL Fission Library. The upgraded LLNL Fission Library was used within MCNPX2.7.0 to run Monte Carlo neutron transport simulations and to verify that results conformed to expectations for criticality benchmarks.

This new FREYA capability enables the simulation of correlations that are not predicted by conventional neutron Monte Carlo codes. For instance, angular correlations of fission neutrons that have been measured in the past could be verified using FREYA [38].

Several improvements of FREYA are planned, such as the addition of more isotopes, and photofission. We are working with the stochastic neutron transport community to make the LLNL Fission Library/FREYA package publicly available to the wider community.

6 Acknowledgments

This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344 and by Lawrence Berkeley National Laboratory under Contract DE-AC02-05CH11231.
A Application programmable interfaces (APIs)

FREYA is accessed via the API to the LLNL Fission Library. There are currently two different APIs in C and in C++. A description of the full interface can be found in Ref. [12]. The parts of the APIs that are relevant to FREYA will be presented here.

A.1 C++ API

The C++ interface to the LLNL fission library consists of a number of C++ functions, the functions that are relevant to FREYA will be described below:

A.1.1 fissionEvent(int isotope, double time, double nubar, double eng, int fissiontype, double* ndir=NULL)

The constructor of class fissionEvent. It is called to generate a fission event. Multiple neutrons and photons are generated and stored in a stack along with their energies, directions and emission times. The arguments of this function are:

- **isotope**: entered in the form $ZA$ (e.g. 94239 for $^{239}$Pu).
- **time**: time of the spontaneous fission.
- **nubar**: user-specified average number of neutrons emitted per fission (e.g. as tabulated in the cross section libraries used by the particle transport code).
- **eng**: energy of the neutron that induces fission.
- **fissiontype**: type of fission: 0) spontaneous fission, 1) neutron-induced fission, 2) photofission.
- **ndir**: normalized incident neutron direction, array with three elements $(u,v,w)$.

Either the average number $\nu$ of neutrons emitted per fission or the energy $eng$ of the fission inducing neutron will be used to determine the number of neutrons sampled, see the function setNudistOption() below. The number of photons sampled only depends on $\nu$. When FREYA is in use, neither $\nu$ or $eng$ is used.

The direction $ndir$ of the incident neutron is only used by the FREYA model. When $ndir$ is set to NULL, FREYA samples the incident neutron direction randomly.

A.1.2 ~fissionEvent() Destructor.

A.1.3 int getNeutronNu()

int getPhotonNu()

These functions return the numbers of fission neutrons and photons emitted in the fission reaction, or -1 if no number could be sampled in the fission library due to lack of data. The reader is referred to the physics reference manual to find the list of isotopes for which sampling will return positive numbers.

A.1.4 double getNeutronEnergy(int index), double getPhotonEnergy(int index)

double getNeutronVelocity(int index), double getPhotonVelocity(int index)

These functions return the energies and velocities of the neutrons and photons.
A.1.5  double getNeutronDircosu(int index), double getNeutronDircosv(int index),
        double getNeutronDircosw(int index)
        double getPhotonDircosu(int index), double getPhotonDircosv(int index),
        double getPhotonDircosw(int index)

These two function families return the direction cosines of the fission neutron and photon velocity vectors along the \( x \), \( y \) and \( z \) axes.

A.1.6  double getNeutronAge(int index)
        double getPhotonAge(int index)

These functions returns the age of the fission neutrons and photons, or -1 if index is out of range. Currently, delayed fission neutrons and photons are not implemented. Thus all fission products are the result of prompt emission.

A.1.7  static void setCorrelationOption(int correlation)

This function is called to set the type of neutron-photon correlation. The argument correlation is set to

0 (default) for no correlation between neutrons and photons.
1  if the total fission neutron energy and total fission photon energy are sampled from normal distributions with means given in Beck et al. [39]. There is no correlation between the number of neutrons and the number of photons.
2  if the total fission neutron energy and total fission photon energy are sampled from normal distributions with means given in Vogt [40]. There is no correlation between the number of neutrons and the number of photons.
3  for the FREYA mode. The neutrons and photons are correlated in number and energy.

When correlation is set to 3 and FREYA can handle the isotope, setNudistOption() and setCf252Option() settings are bypassed. FREYA computes all secondary observables independently.

A.1.8  static void setNudistOption(int nudist)

This selects the data to be sampled for the neutron number distributions in the case of neutron-induced fission. If there are no data available, then the Terrell approximation is used for all cases. The argument nudist takes 4 values.

0  Use the fit to the Zucker and Holden tabulated \( P(\nu) \) distributions as a function of energy for \( {}^{235}\text{U}, {}^{238}\text{U} \) and \( {}^{239}\text{Pu} \) [41].
1  Use fits to the Zucker and Holden tabulated \( P(\nu) \) distribution as a function of energy for \( {}^{238}\text{U} \) and \( {}^{239}\text{Pu} \) [41], and a fit to the Zucker and Holden data [41] as well as the Gwin, Spencer and Ingle data (at thermal energies) [42] as a function of energy for \( {}^{235}\text{U} \).
2  Use the fit to the Zucker and Holden tabulated \( P(\nu) \) distributions as a function of \( \nu \) [41]. The \( {}^{238}\text{U} \) fit is used for the \( {}^{232}\text{U}, {}^{234}\text{U}, {}^{236}\text{U} \) and \( {}^{238}\text{U} \) isotopes, the \( {}^{235}\text{U} \) fit for \( {}^{233}\text{U} \) and \( {}^{235}\text{U} \), the \( {}^{239}\text{Pu} \) fit for \( {}^{239}\text{Pu} \) and \( {}^{241}\text{Pu} \).
3 (default) Use the discrete Zucker and Holden tabulated \( P(\nu) \) distributions and corresponding values of \( \nu \) [41]. Sampling based on the incident neutron \( \nu \). The \( {}^{238}\text{U} \) data tables are used for the \( {}^{232}\text{U}, {}^{234}\text{U}, {}^{236}\text{U} \) and \( {}^{238}\text{U} \) isotopes, the \( {}^{235}\text{U} \) data for \( {}^{233}\text{U} \) and \( {}^{235}\text{U} \), the \( {}^{239}\text{Pu} \) data for \( {}^{239}\text{Pu} \) and \( {}^{241}\text{Pu} \).
A.1.9  static void setCf252Option(int ndist, int neng)

This function is specific to the spontaneous fission of $^{252}\text{Cf}$. It selects the data to be sampled for the neutron number and energy distributions and takes the following arguments:

ndist: Sample the number of neutrons
0 (default) from the tabulated data measured by Spencer [43].
1 from the Boldeman data [44].

neng: Sample the spontaneous fission neutron energy
0 (default) from the Mannhart-corrected Maxwellian spectrum [45].
1 from the Madland-Nix model spectrum [32].
2 from the Watt spectrum [46] fit attributed to Fröhner [47].

A.1.10  static void setRNGf(float (*funcptr) (void)), static void setRNGd(double (*funcptr) (void))

This function sets the random number generator to the user-defined one specified in the argument. If either setRNGf() or setRNGd() are not specified, the default system call srand48 is used. The arguments are random number generator functions that returns variables of type float and double respectively. The C++ language imposes that the function pointer in argument be either a global function or a static function of another class.

A.1.11  void getFREYAerrors(int* length, char* errors)

This function returns potential error messages generated by FREYA. The arguments of this function are

length: length of array of characters.
errors: pointer to an allocated array of characters.

A.1.12  void setFREYAdatapath(char* datapath)

This function is called to set the path to the directory where the data required by FREYA is located. It takes the following argument:

path: pointer to a character string containing the path to the directory containing the data required by FREYA.

A.2  C API

The C interface to the LLNL fission library consists of 27 C functions, the functions that are relevant to FREYA will be described below:

A.2.1  void genspfissevt_(int *isotope, double *time)

This function is called to trigger a spontaneous fission event. Multiple neutrons and photons are generated and stored in a stack along with their energies, directions and emission times. The arguments of this function are
isotope: entered in the form ZA (e.g. 94239 for $^{239}$Pu)
time: time of the spontaneous fission event.

The generated neutrons and photons, along with their properties, will be lost upon the next call to genspfissevt() or genfissevt(). Therefore, they must be retrieved by the caller before a subsequent call to one of these functions, using the appropriate functions described below.

A.2.2 void genfissevtdir(int *isotope, double *time, double *nubar, double *eng, double *ndir)
This function is called to trigger a neutron-induced fission event. In addition to the two arguments above for genspfissevt(), the fission-inducing neutron is characterized by:

nubar: user-specified average number of neutrons emitted per fission (e.g. as tabulated in the
cross section libraries used by the particle transport code)
eng: energy of the neutron that induces fission.
ndir: normalized incident neutron direction, array with three elements (u,v,w).

Either the average number \( \nu \) of neutrons emitted per fission or the energy \( \text{eng} \) of the fission inducing neutron will be used to determine the number of neutrons sampled, see the function setnudist() below. The number of photons sampled only depends on \( \nu \). Similar to genspfissevt(), the generated neutrons and photons are lost upon subsequent calls to genspfissevt() or genfissevt().

The direction \( \text{ndir} \) of the incident neutron is only used by the FREYA model.

A.2.3 void genfissevt(int *isotope, double *time, double *nubar, double *eng)
Same as call to genfissevtdir() but FREYA samples the incident neutron direction randomly.

A.2.4 int getnnu()
int getpnu()
These functions are the counterparts of those in Sec. A.1.3.

A.2.5 double getneng(int *index), double getpeng(int *index)
double getnvel(int *index), double getpvel(int *index)
These functions are described in Sec. A.1.4.

A.2.6 double getneng(int *index), double getpeng(int *index)
double getnvel(int *index), double getpvel(int *index)
These functions are identical to those in Sec. A.1.4.

A.2.7 double getndircosu(int *index), double getndircosv(int *index), double getndircosw(int *index)
double getpdircosu(int *index), double getpdircosv(int *index), double getpdircosw(int *index)
These functions are explained in Sec. A.1.5.
A.2.8 double getnage_(int *index)
    double getpage_(int *index)

These functions are the counterparts of those in Sec. A.1.6.

A.2.9 void setcorrel_(int *correlation)

This function is explained in Sec. A.1.7.

A.2.10 void setnudist_(int *nudist)

This function has its counterpart in Sec. A.1.8.

A.2.11 void setcf252_(int *ndist, int *neng)

This function is described in Sec. A.1.9.

A.2.12 void setrngf_(float (*funcptr) (void)), void setrngd_(double (*funcptr) (void))

These functions have their counterpart in Sec. A.1.10.

A.2.13 void getfreya_errors(int* length, char* errors)

This function has a counterpart in Sec. A.1.11.

A.2.14 void setfreyadatapath(char* datapath)

The counterpart of this function is described in Sec. A.1.12.
